PAPER

A rapid response process for evaluating causes of extreme temperature events in the United States: The 2023 Texas/Louisiana heat wave as a prototype

Rapid Response Framework

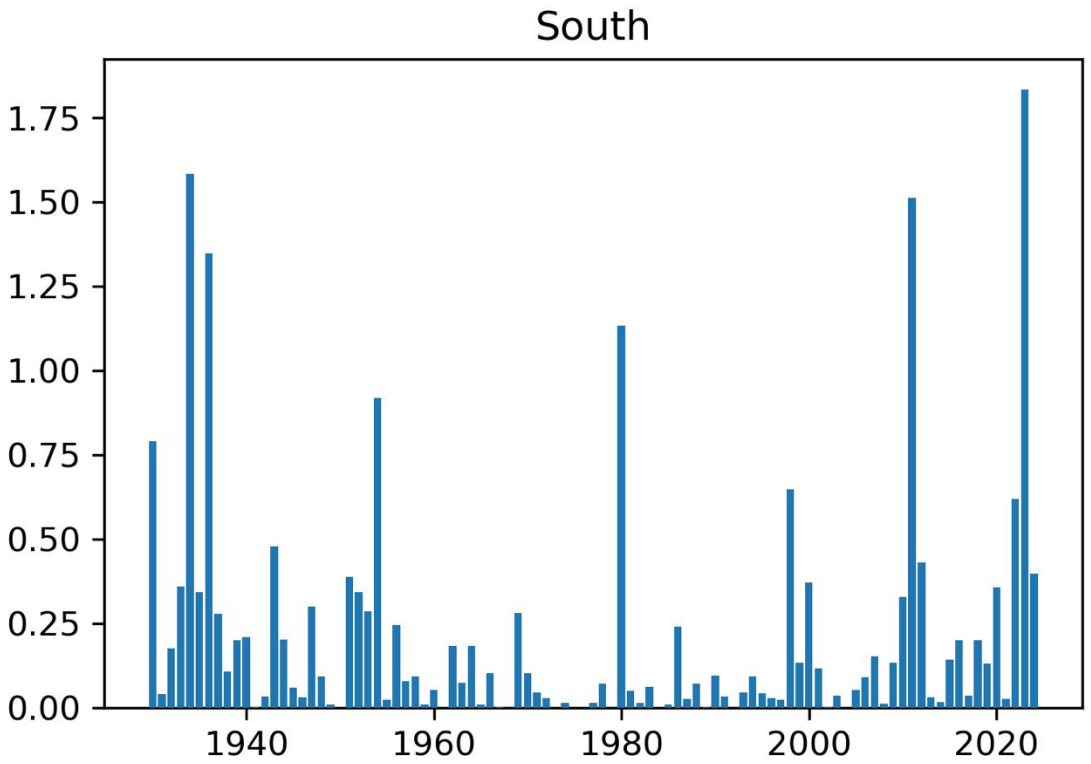

- Monitoring and Triggering
  - 5-day 5-year events are the benchmark.
- Observational Analysis
  - GPD shows how the rarity of the event has changed between 1951–1980 and 1981–2020.
- Synoptic Analysis
  - Identify climate variability drivers using teleconnection patterns.
- Model Analysis
  - Compare the event in SPEAR seasonal forecasts vs uninitialized SPEAR simulations
  - Compare the rarity of the event in SPEAR simulations between 1951–1980 and 1981–2020

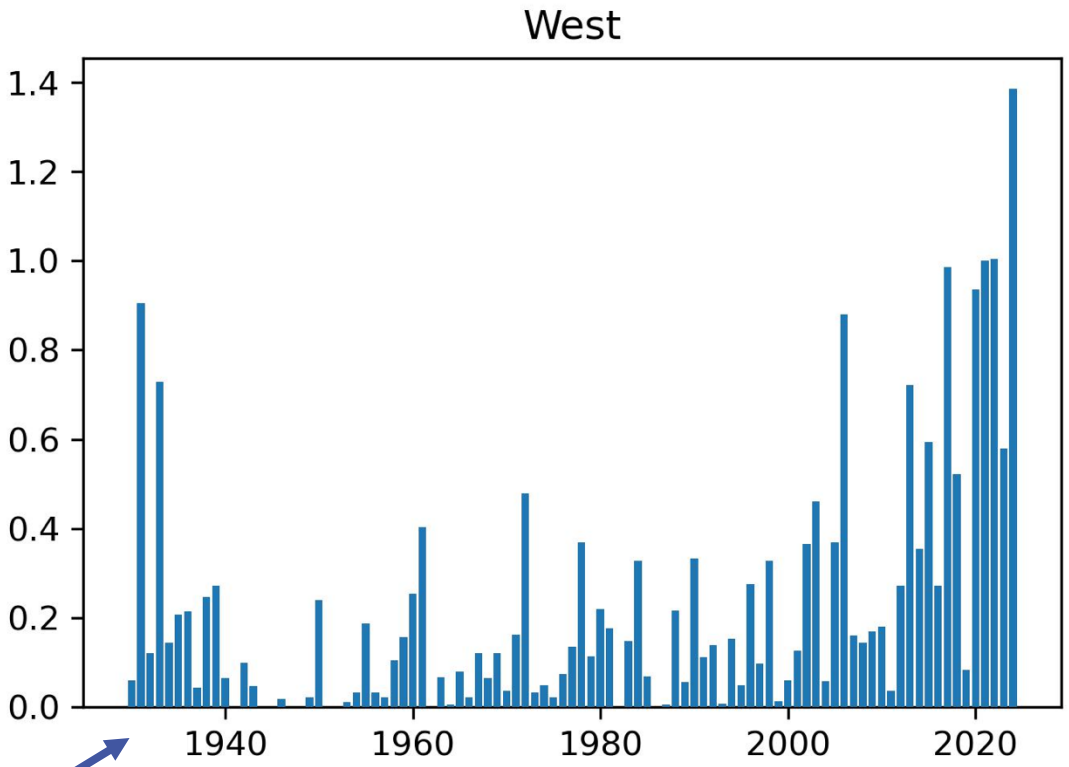

Monitoring and Triggering

Summary

- The Western United States experienced an acute heat wave July 4–13 2024.
- A secondary heat wave followed July 21–26.
- California was particularly hard hit with record temperatures set across the state for the month of July in large part due to these two heat waves.
- Large positive values of the Pacific–North American pattern, North Atlantic Oscillation, and Arctic Oscillation all contributed to the heat.
- Model analysis is in progress to quantify the effect of climate change.
