Research Questions

1. How sensitive is SnowModel snowpack evolution to different percolation decisions and parameterizations?
2. How transferable are different percolation routines between climates and what does this transferability mean?
3. Can overall model performance be improved for all climates?

Model adaptation

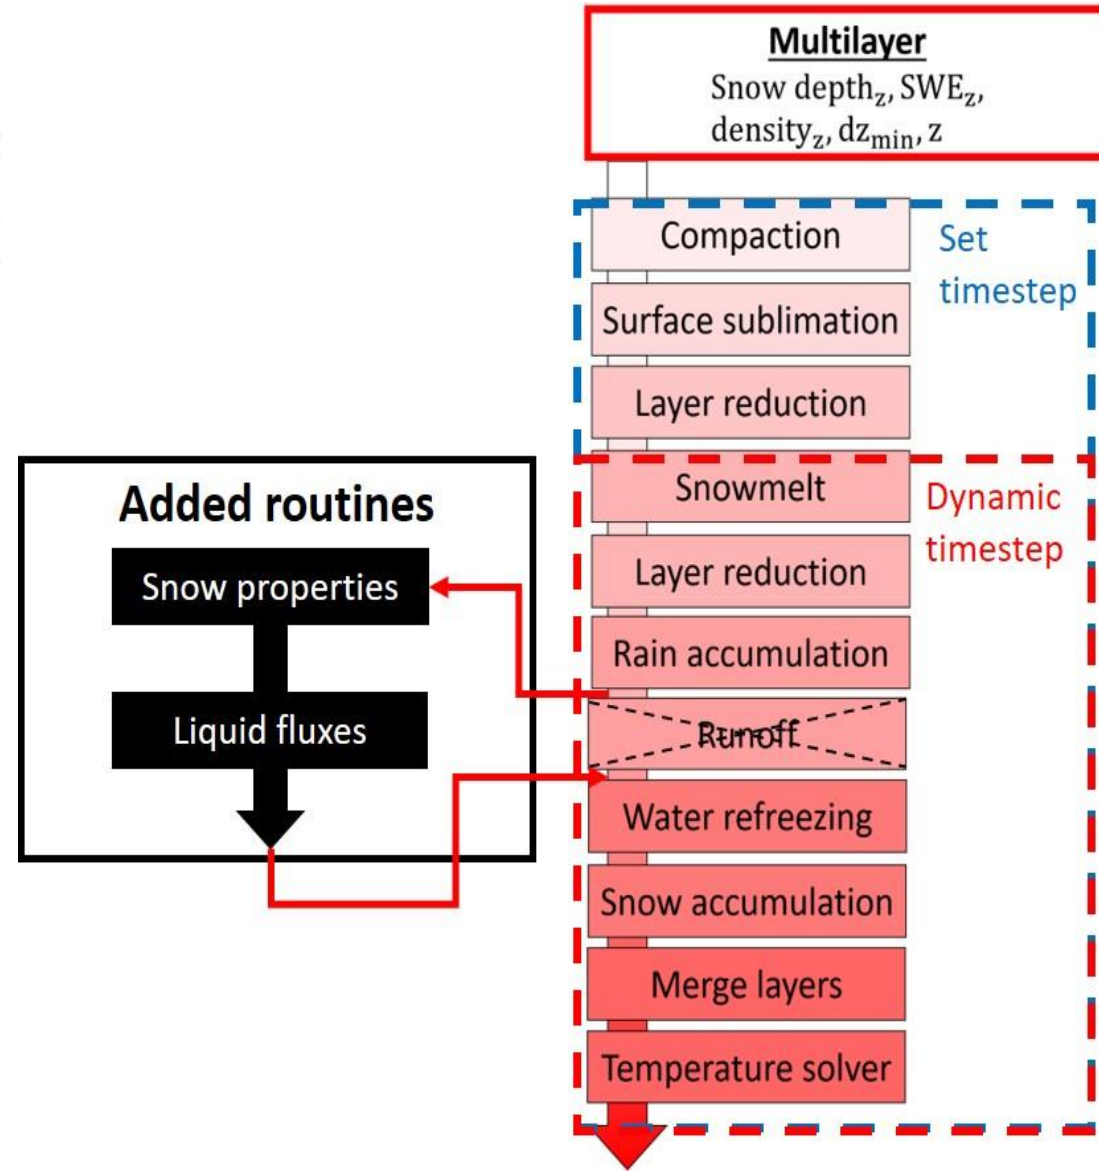

Cold, dry snow

From Thomas Kaempfer, SLF

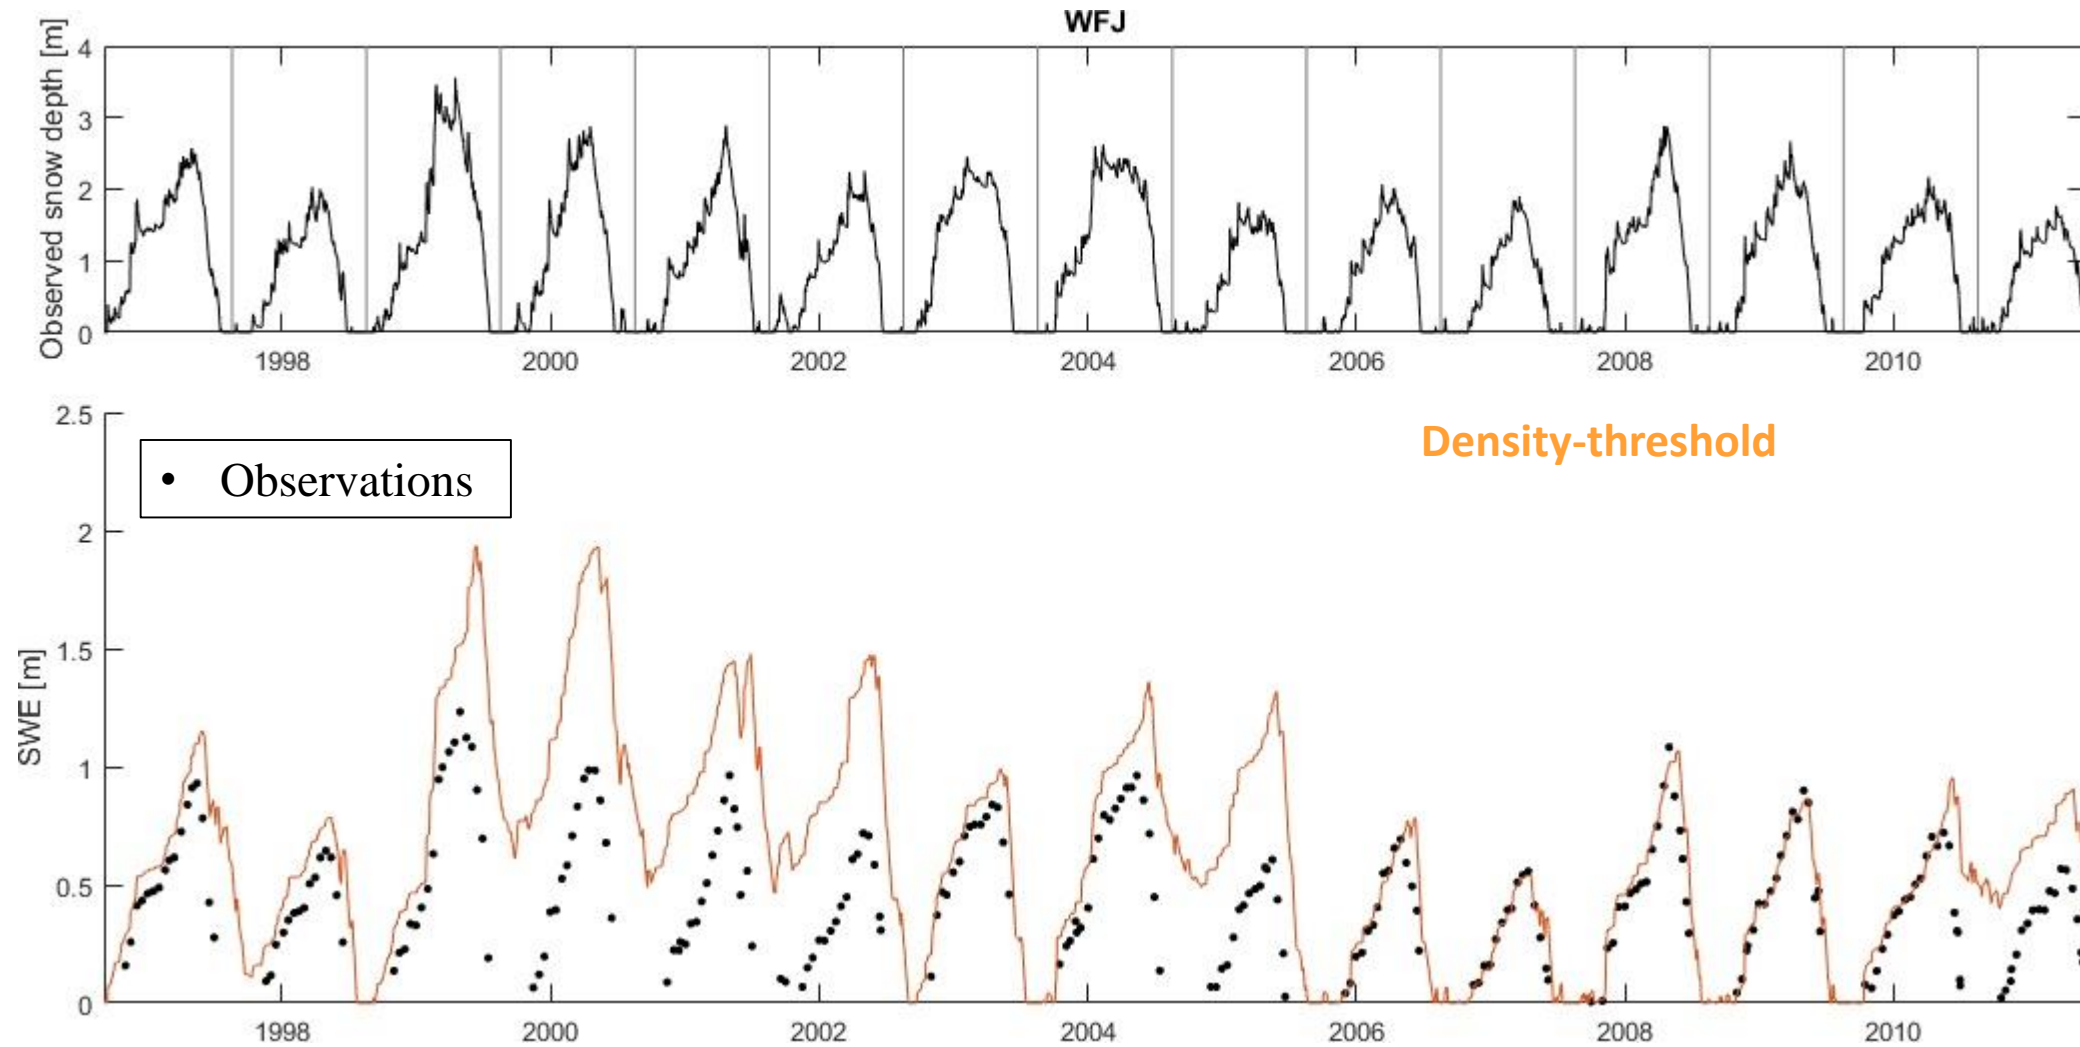

Warm, wet snow

Study domains

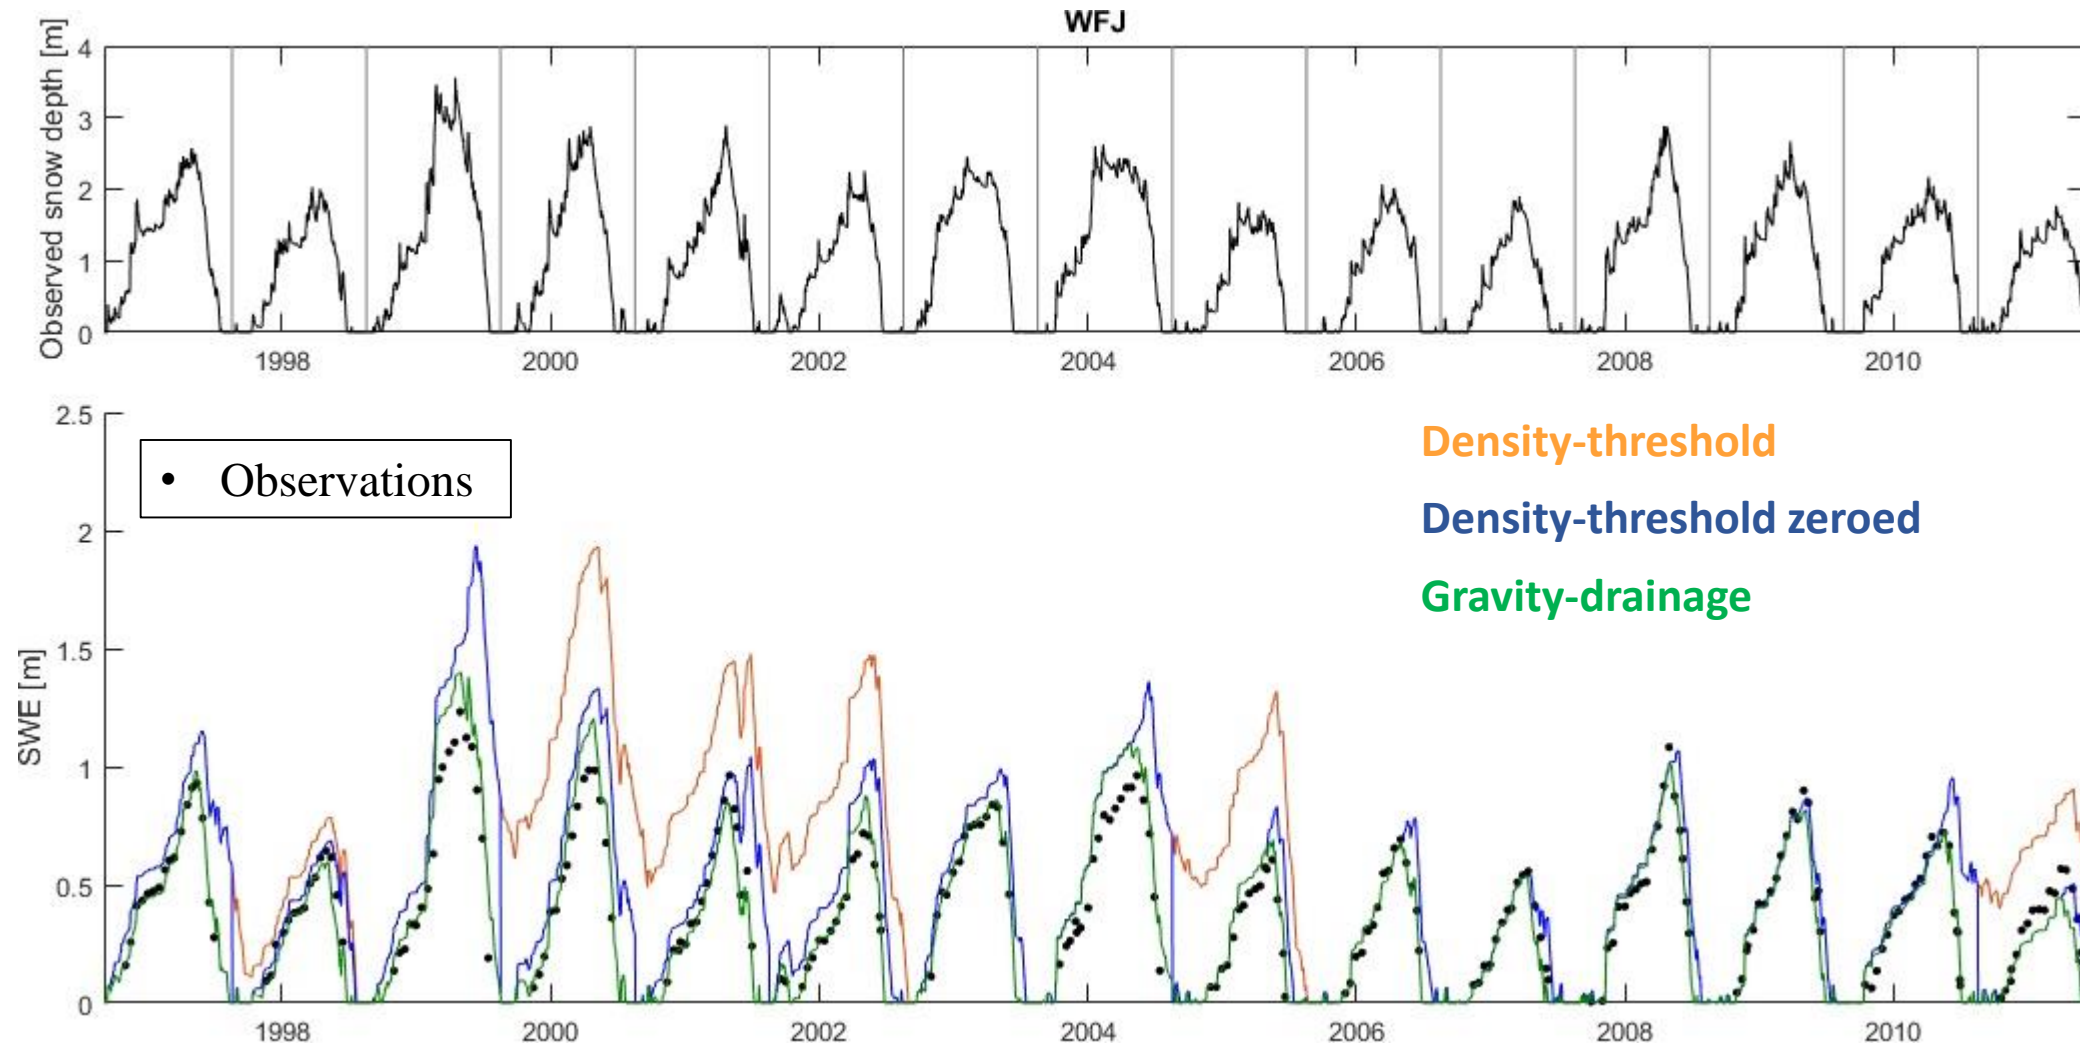

Default simulations

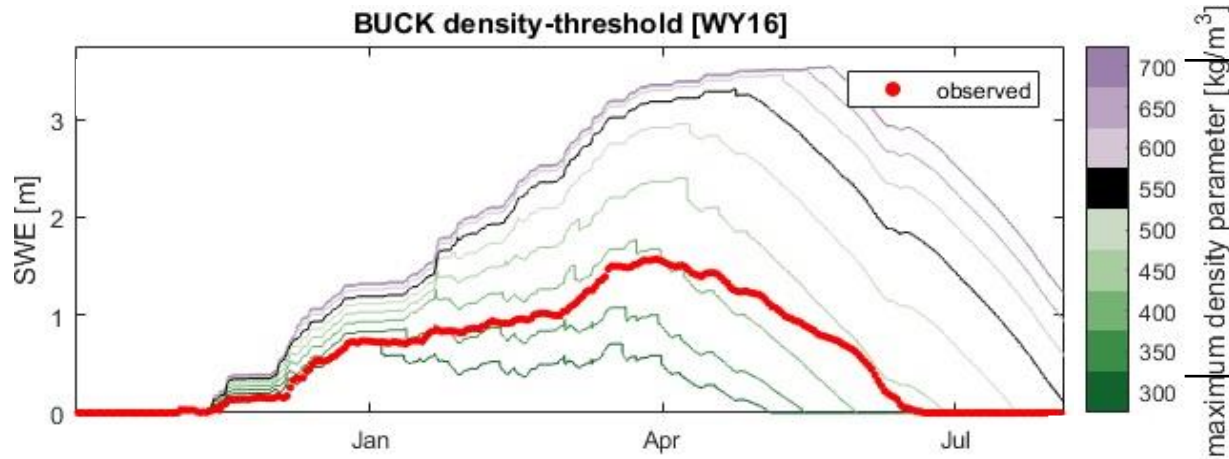

Default simulations

Default simulations

Default simulations and parameter sensitivity

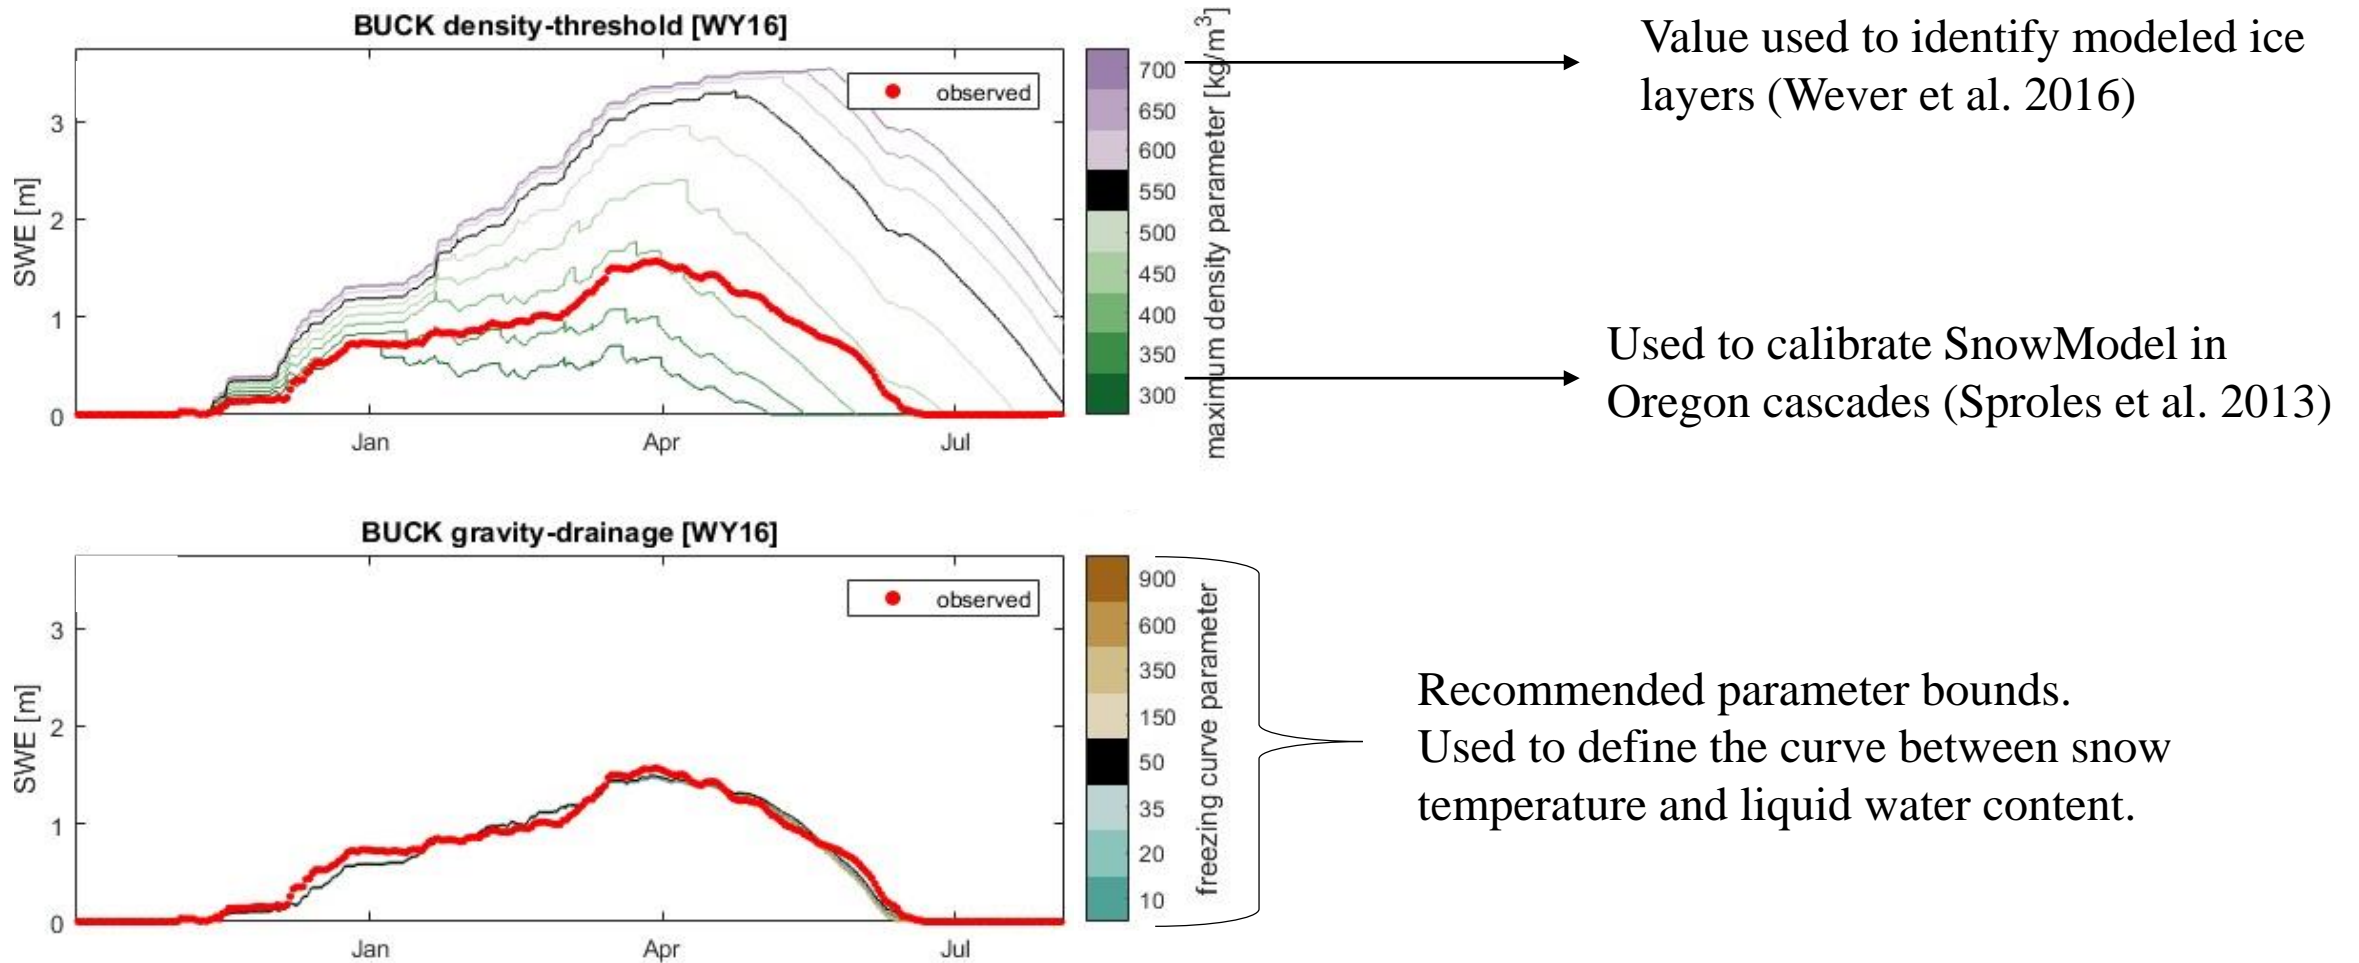

Value used to identify modeled ice layers (Wever et al. 2016)

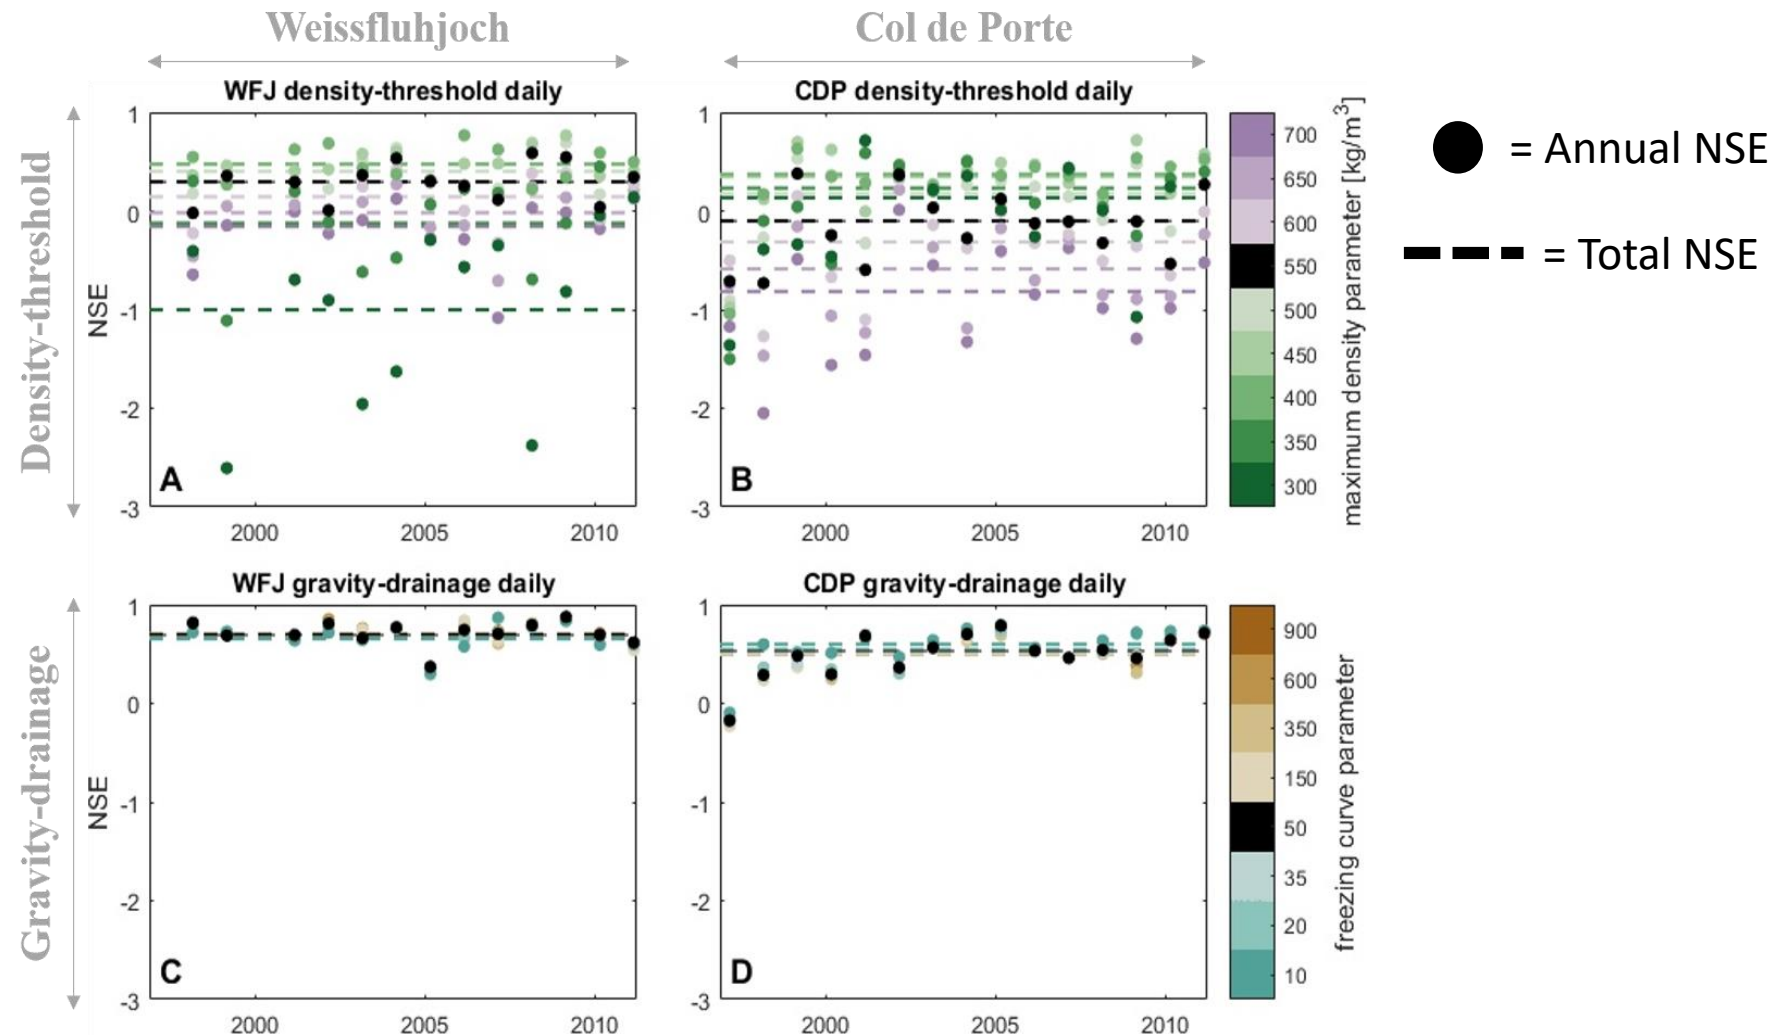

Used to calibrate SnowModel in Oregon cascades (Sproles et al. 2013)

Study conclusions

- Percolation in accordance to a physically-motivated percolation routine outperforms the parameterized routine
- The physically-motivated percolation scheme displayed reduced parameter sensitivity
- Transferability in this experiment is indicative of process misrepresentation and model errors
- Transferability in this experiment is severely compromised when moving the parameterized routine to extreme climates

Lessons learned

- Hardcoded and “black-box” modeling decisions make errors in models difficult to attribute
- Models developed for a particular climate may not always be applicable in a different climate or period with climate change (“shantytown syndrome”)
- Tradeoffs between model complexity and utility should be considered in the development process.

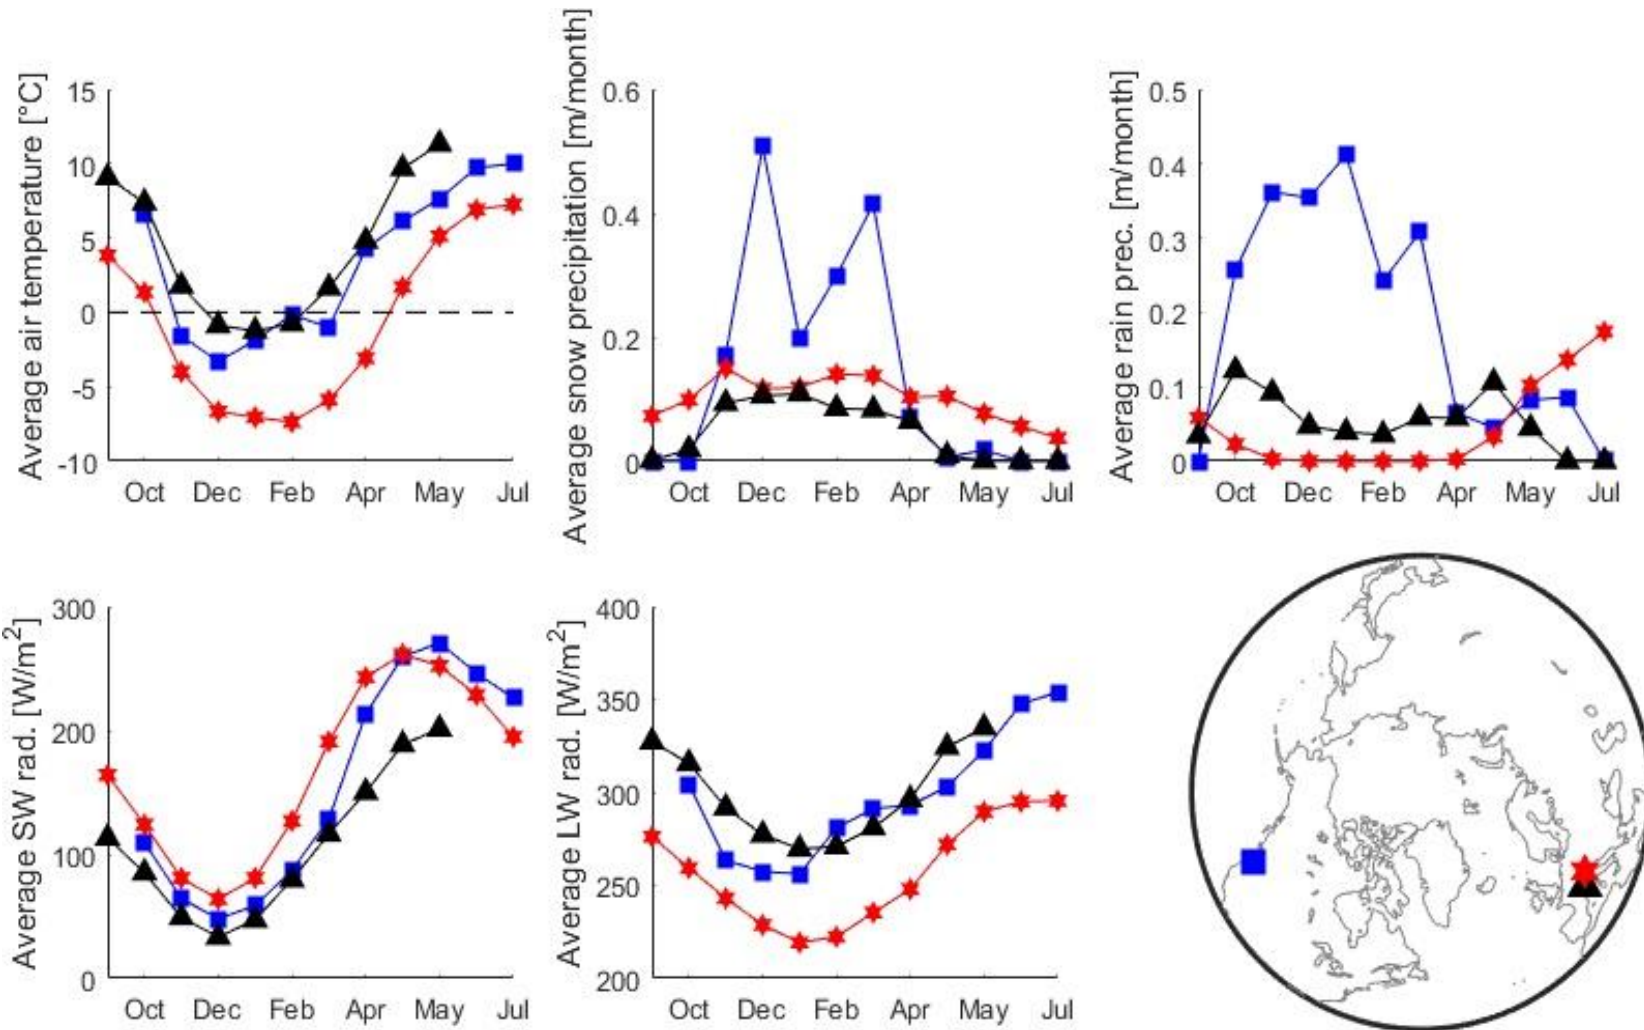

Thank you
