P.54: Comparison of 24 May 2011 Genesis and Evolution of Simulated Tornado-Like Vortices Using Various Microphysics Schemes with 1-km Grid Resolution

Derek Stratman1,2 and Keith Brewster1
1Center for Analysis and Prediction of Storms
2School of Meteorology, The University of Oklahoma

Introduction
- On 24 May 2011, Western and Central Oklahoma experienced an outbreak of tornadoes, including one rated EF5 (S1) and two rated EF4 (S2 and S3).
- The extensive observation network across Oklahoma during the 2011 Spring makes this an ideal case to explore model forecast capabilities applicable to the Warn-on-Forecast (WoF) concept (Stensrud et al., 2009, 2013).
- The Center for Analysis and Prediction of Storms (CAPS) real-time forecasting system had good success in simulating these storms, but improvements might be expected using more sophisticated microphysics schemes or an ensemble of models with microphysics diversity.
- The aim of this study is to examine the impact of using four different microphysics parameterization schemes on the genesis and evolution of simulated tornado-like vortices (TLVs) via the updraft helicity (UH) field as compared to each other and reality.
- Similar to hurricane track errors (e.g., Xue et al., 2013), UH track errors are computed to assess model performance.

Observational Data
- NWS METAR and Oklahoma Mesonet data
- WSR-88D radar data (KTFL, KFDR, KVN, KICT, KDCC, KFWS, and KINX)
- Collaborative Adaptive Sensing of the Atmosphere (CASA) radar data (KCYR, KSAO, KWE, and KRSP)
- Tornado tracks estimated from National Weather Service damage surveys

Model Details
- Advanced Regional Prediction System (ARPS) developed at CAPS
- 32x33x53-km domain
- 1-km horizontal grid spacing
- Minimum vertical grid spacing of 20 m
- \( dt_{x,y} = 0.5 \) s
- 4th order momentum advection
- 12-km North American Mesoscale (NAM) model output used for background fields and lateral boundary conditions

Results
- **1 – 6-km UH**
  - For S1, MP2 is fastest, but closest to tornado tracks at any time.
  - For S1, MP8 is nearest to tornado tracks at same time.
  - For S2, all simulations produce a UH track > 10 km to the NW.
  - For S3, MP5, MP8, and MP9 emulate the tornado track well.
- **0 – 1-km UH**
  - For S1, similar to 1 – 6-km UH’s results, but UH centers are now closer to tornado tracks.
  - For S2, not much in range of interest at same time, but at any time, some UH centers exist > 10 km to the NW.
  - For S3, MP8 is best, but all simulations perform well.

Summary and Future Work
- Evaluating simulated TLVs via the UH field with respect to estimated real tornado points from the 24 May 2011 tornado outbreak has proven to be an effective measure of model successes and failures.
- This study helps define expected error bounds for WoF ensemble concept.
- Explore other variables (e.g., vorticity, w-wind, etc.) for center tracking.
- Investigate the possibility of using 3DVAR/IAU analysis instead of microphysics points for verification.
- Apply this verification technique to the Storm Prediction Center’s storm reports database.
