Overview & Objective

TWO PRODUCTS ISSUED ON DIFFERENT SCALES:

- 1) National Weather Service (NWS) Tornado Warning
 - Short-fuse, polygon-based (since 2007) alert for a forecaster-defined threat area
- 2) NWS Storm Prediction Center (SPC) Day 1 Outlook
 - Daily guidance on locations of forecasted high-risk weather across the continental United States

STUDY OBJECTIVE:

Using Geographic Information Systems (GIS), spatial characteristics from these forecaster-defined warnings can be used to develop associations between warnings and other factors.

This study provides an empirical analysis of Tornado Warning area, storm motion, and warning performance within different SPC Day 1 Outlook tornado probabilities.

Polygon Area by Tornado Risk

Warnings classified within higher tornado risk categories cover a larger area.

Permutation testing showed statistical significance between areas at the 99% confidence interval for 19 of the 21 comparison groups. The two pairs of comparison groups which did not meet this requirement were:

- 1) 15% vs. 30% - Significantly different at the 85% confidence interval
FACTOR: Insufficient sampling of warnings within 30% risk (~2.5% of study)
- 2) ≤ 250 mi. & 2% - Exceeded population mean 83% of time
FACTOR: 64% of warnings classified in the ≤ 250 mi. group were < 50 mi. from the 2% risk category

Mean Warning Area By Tornado Risk Category

Category	Warning Frequency	Mean Area (Sq. Mi.)
> 250 mi.	418	279.62
≤ 250 mi.	578	359.66
2%	1705	357.19
5%	3048	399.96
10%	1242	430.86
15%	740	494.09
30%	192	530.80

Data & Methods

Study Timeframe: 12z 01 January 2008 - 12z 01 January 2010

Totals: 7923 Tornado Warnings 3228 Tornado Events
3645 SPC Tornado Probability Forecasts

THREE SPATIAL LAYERS FOR ANALYSIS

1) SPC TORNADO PROBABILITIES

Five SPC probability groups in the dataset:

- 2%, 5%, 10%, 15%, 30%

Two additional classification groups added for warnings that fall outside all risks:

- Within 250 mi. from risk (≤ 250 mi.)
- Greater than 250 mi. from risk (> 250 mi.)

2) TORNADO WARNINGS

Classified as a point based on the TIME...MOT...LOC inputs in the warning

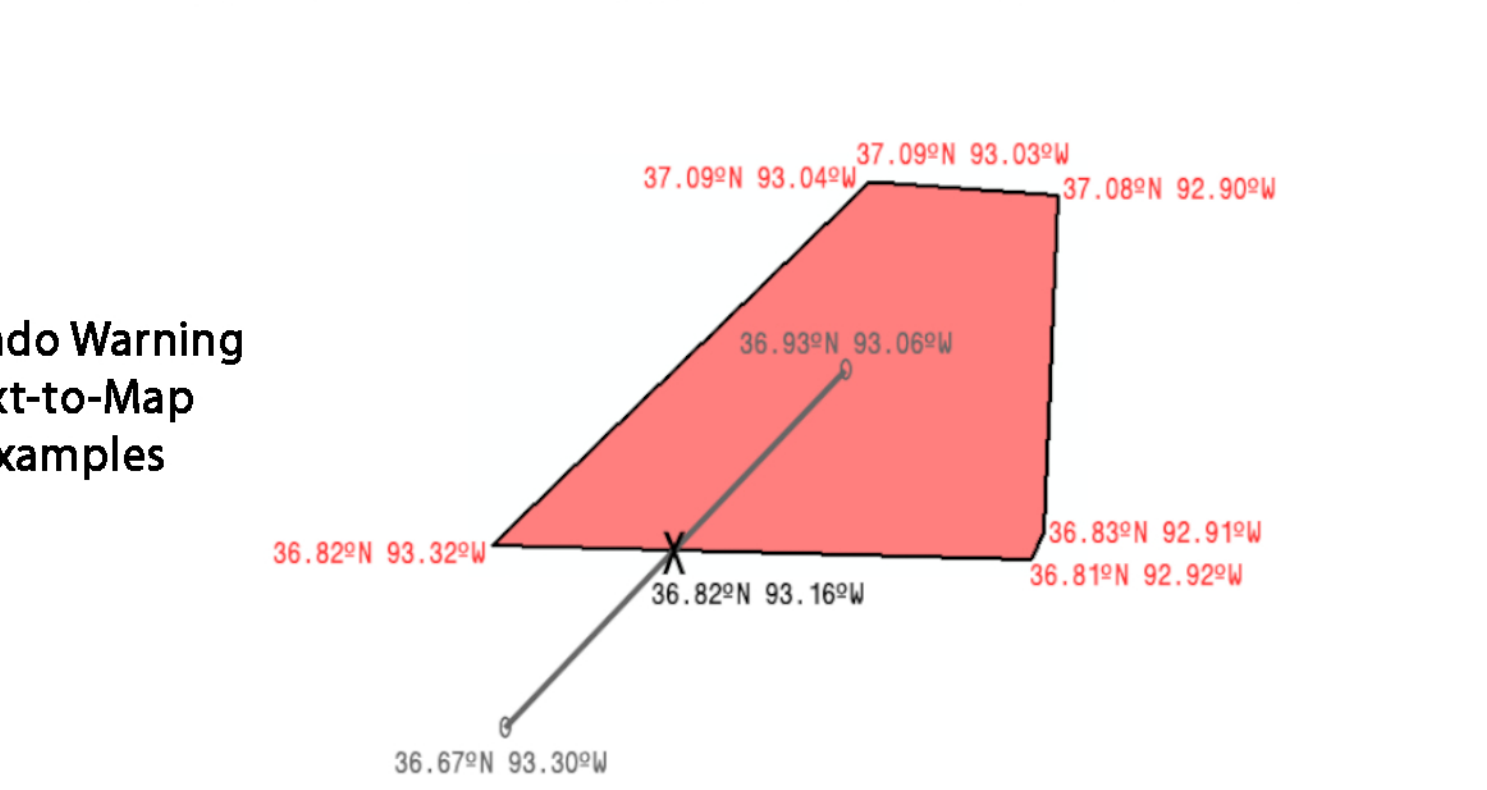

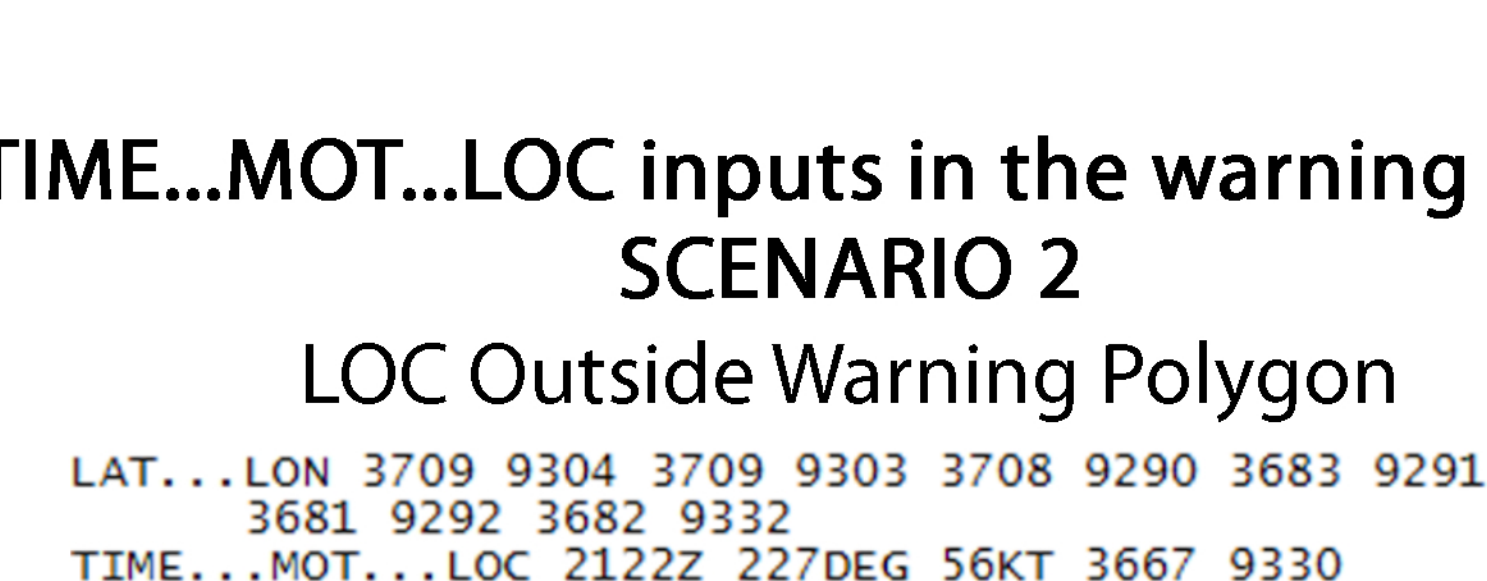

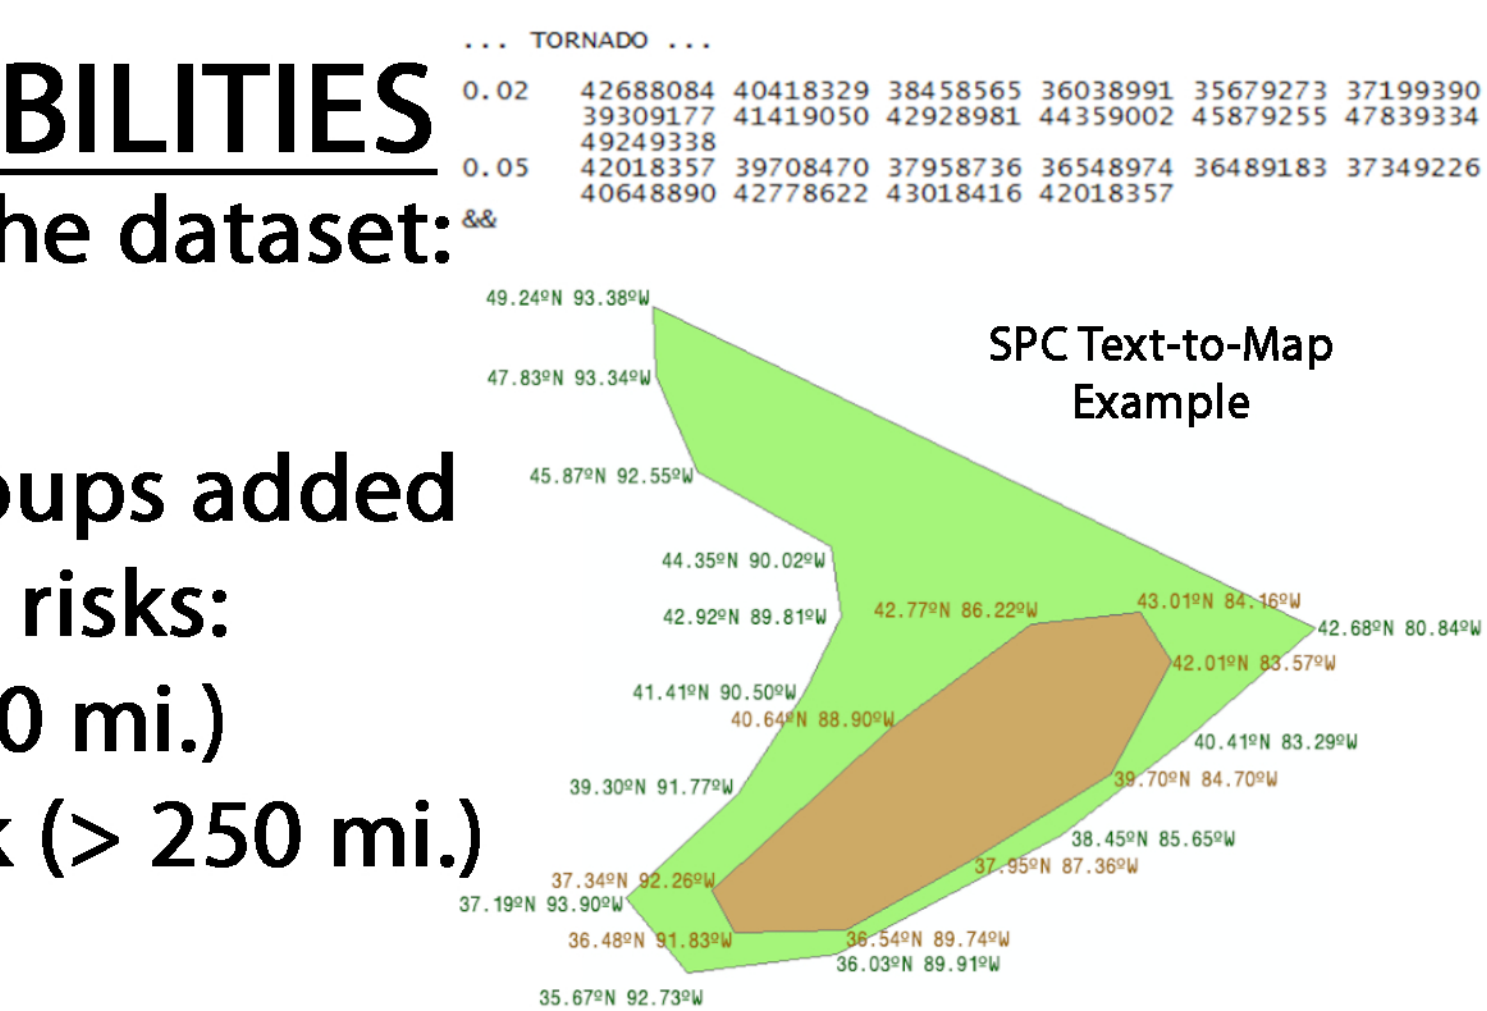

SCENARIO 1	SCENARIO 2
LOC Inside Warning Polygon	LOC Outside Warning Polygon
LAT...LON 3599 9296 3555 9335 3568 9361 3610 9330	LAT...LON 3709 9304 3709 9303 3708 9290 3683 9291
TIME...MOT...LOC 2147Z 217DEG 45KT 3570 9345	TIME...MOT...LOC 2122Z 227DEG 56KT 3667 9330

Action: The LOC will act as the warning location point

3) TORNADO EVENTS

Classified as a point based off the latitude/longitude location of first tornado touchdown

Action: A line will be drawn between the LOC and the polygon centroid. The intersection will be the warning location point

Storm Motion by Tornado Risk

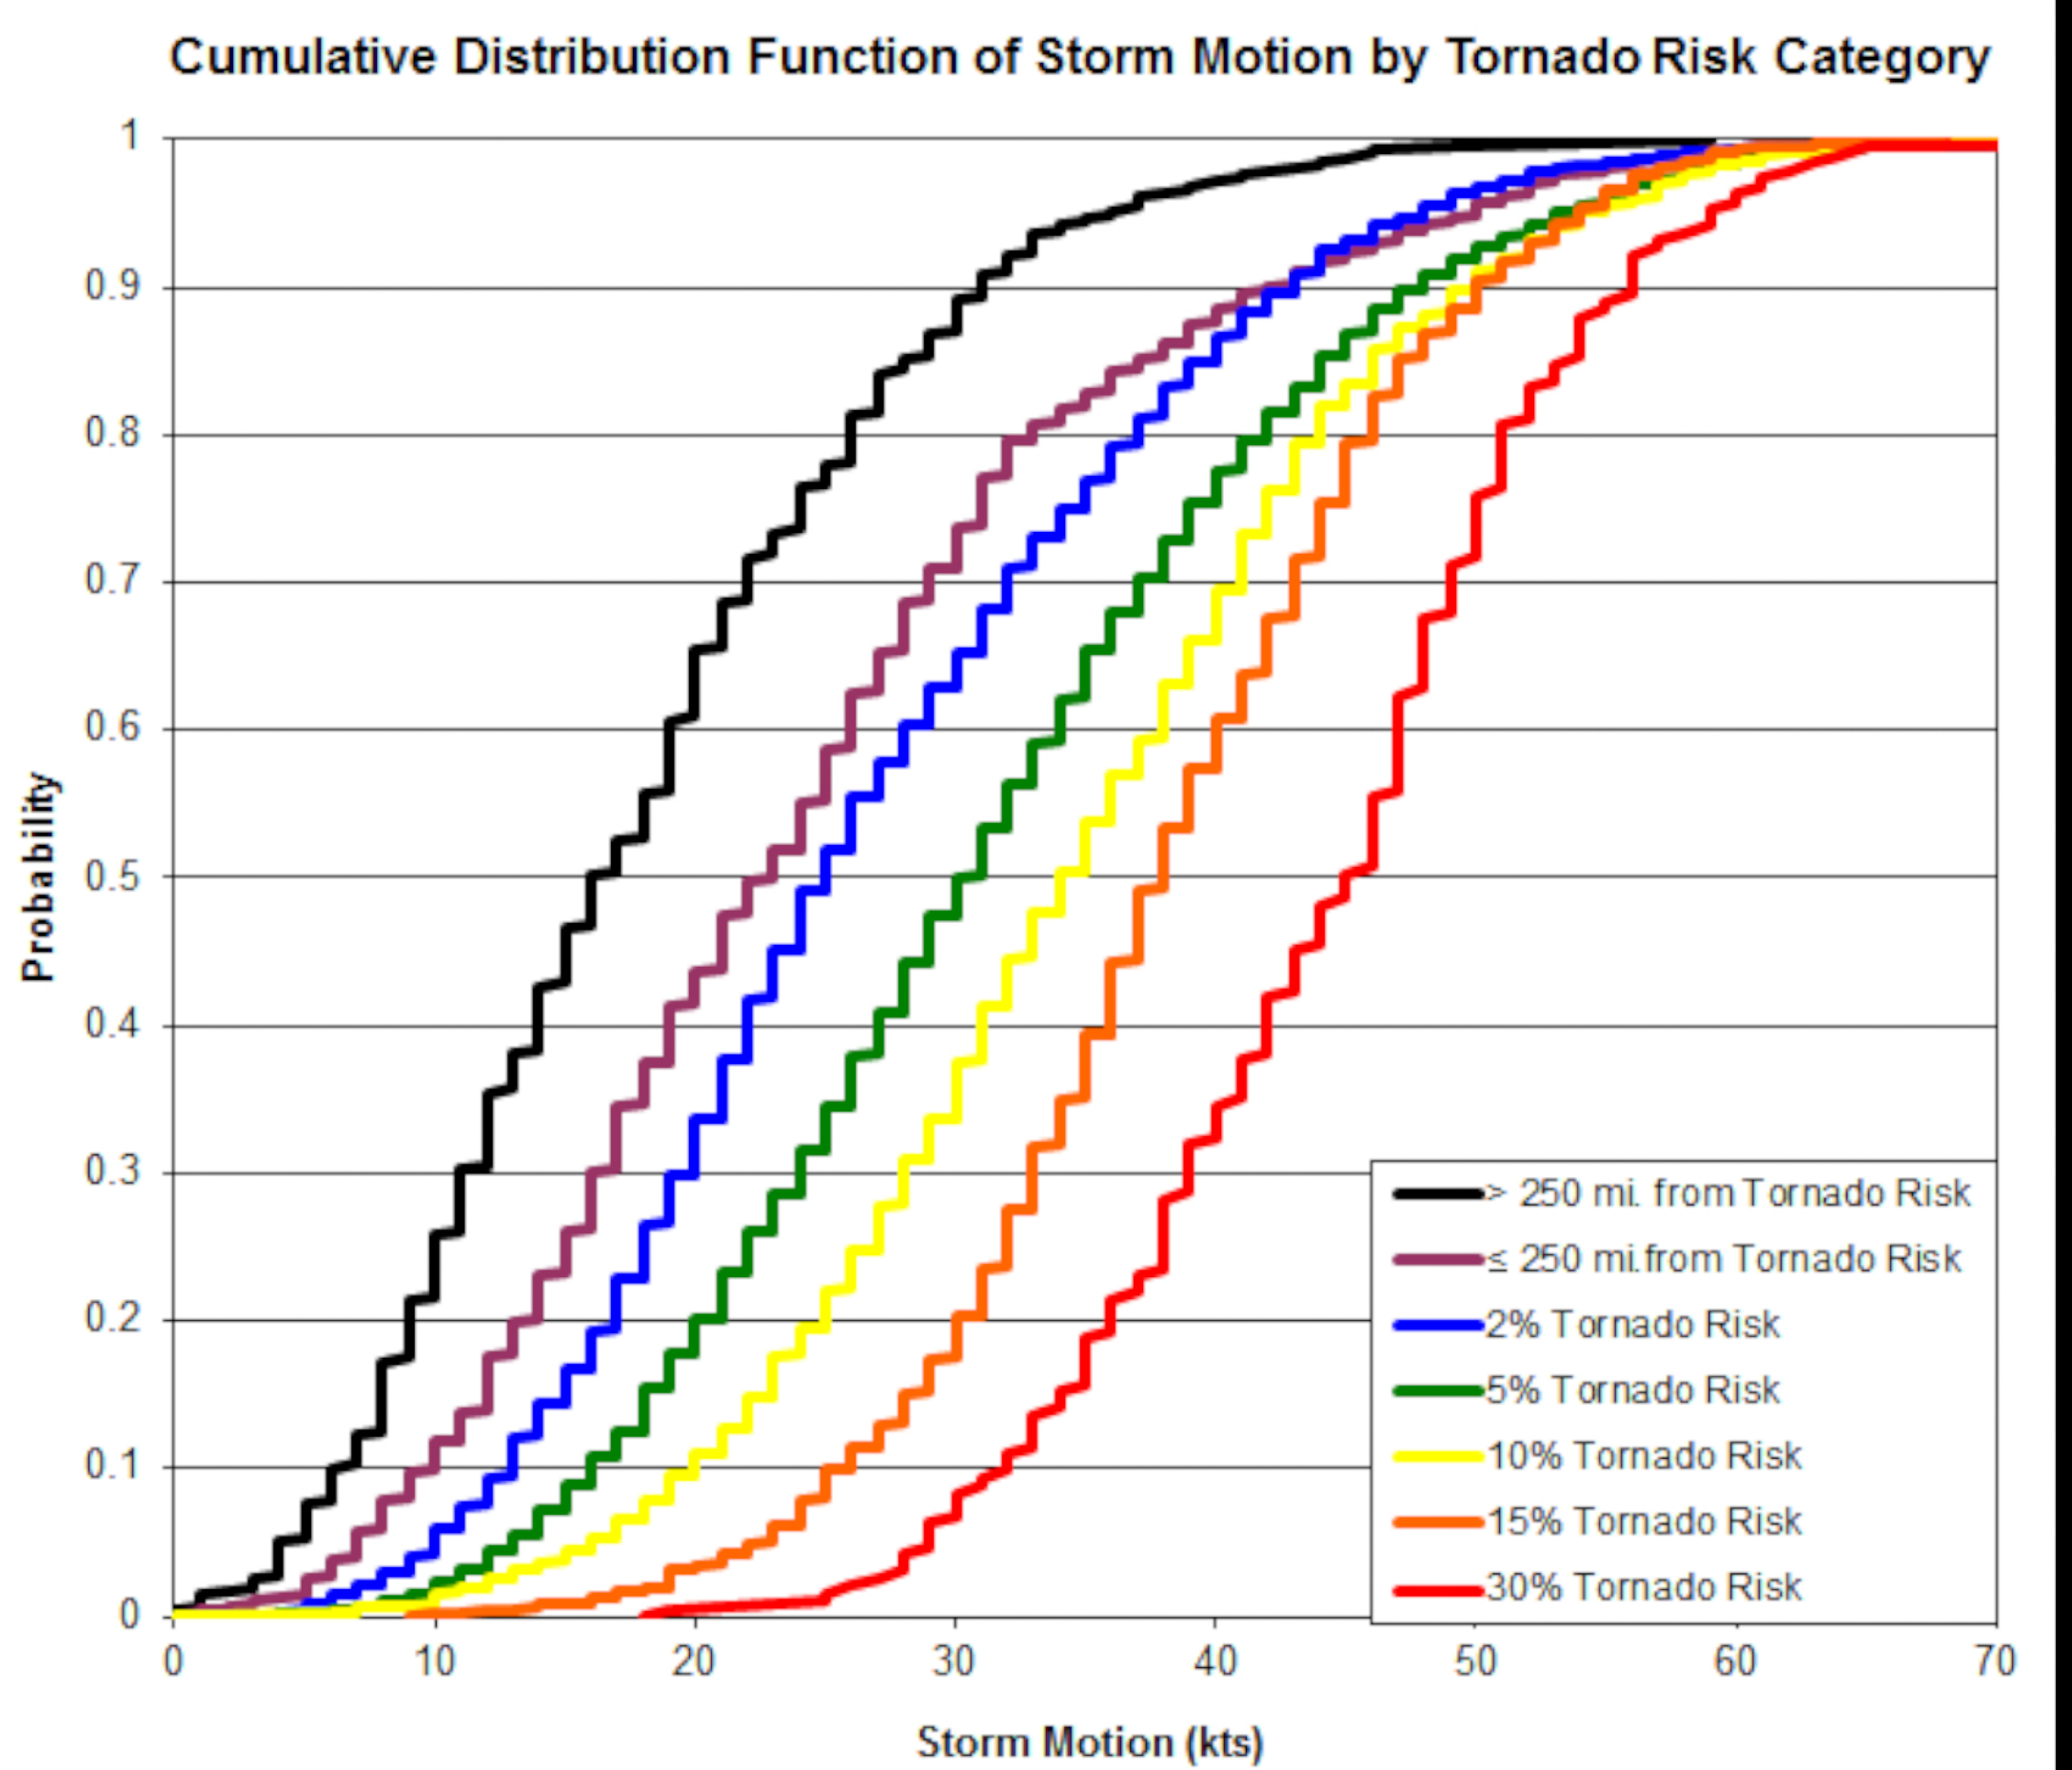

Warnings classified within higher tornado risk categories had faster storm motions.

Permutation testing showed statistical significance between speeds in different categories at the 99% confidence interval for all 21 possible comparison groups.

Faster motions can be a contributing factor in the size of Tornado Warnings. Longer warning polygons would be necessary as a faster moving storm would cover a greater area in a shorter time.

Mean Storm Motion by Tornado Risk Category

Category	Warning Frequency	Mean Storm Motion (kts)
> 250 mi.	418	17.85
≤ 250 mi.	578	24.26
2%	1705	26.67
5%	3048	31.33
10%	1242	34.54
15%	740	37.96
30%	192	44.18

Performance by Tornado Risk

Three performance metrics were calculated:

- Probability of Detection (POD)
- False Alarm Ratio (FAR)
- Critical Success Index (CSI)

All three metrics showed an overall improvement in performance for warnings classified within higher tornado risk categories.

OVERALL IMPROVEMENT:

POD: + 0.539

FAR: - 0.234

CSI: +0.257

2x2 Contingency Table
OBSERVED

		YES	NO
FORECAST	YES	A	B
	NO	C	D

$$\text{POD} = \frac{A}{A+C}$$

$$\text{FAR} = \frac{B}{A+B}$$

$$\text{CSI} = \frac{A}{A+B+C}$$
