

Analysis of precipitation-related climate indices projected for Central/Eastern Europe using bias-corrected ENSEMBLES simulations

DEPARTMENT OF METEOROLOGY, EÖTVÖS LORÁND UNIVERSITY, H-1117, BUDAPEST, Pázmány st. 1/a, HUNGARY, E-mails: prita@nimbus.elte.hu, bartholy@caesar.elte.hu, kisanna610@gmail.com

ABSTRACT

In order to support regional adaptation and mitigation strategies, global climate model (GCM) simulation results must be downscaled for local analysis, which can better serve agriculture-related and users' needs. This is especially important in case of precipitation due to the large temporal and spatial variability. Both the high potential risks of drought events on agricultural production, and the possible flood risks in urban areas, as well as the increasing frequency of extreme events over shorter periods, also highlight the importance of this research.

On the basis of evaluating raw RCM projections and of ENSEMBLES model experiments for the period 1951–2000, it was found that the 12 GCMs considered, including daily precipitation values (Held et al., 2009), simulated values usually significantly overestimate the observations in the Carpathian Basin, except in summer. No steady underestimations were found (Pongrácz et al., 2011). These findings of the raw data were confirmed by the bias-corrected ENSEMBLES distribution functions by fitting to the observed distribution (Forniari & Haes, 2009). Then, the calculated bias-correcting factors are applied to the outputs of the ENSEMBLES experiments for the period 2071–2100. According to the GCM A1B emission scenario (Nakicenovic & Swart, 2000), according to which CO₂ concentration by 2100 is estimated to exceed 700 ppm (more than twice of pre-industrial level), the projected changes in precipitation are significant (Kert et al., 1999) are calculated from the corrected precipitation data sets for each grid point. Projected seasonal changes for 2071–2100 are determined relative to the 1961–1990 reference period and presented in this analysis.

ENSEMBLES outputs (<http://ensembles-eu.metoffice.com>)

For 1951–2010 using SRES A1B scenario

Held, M. J., et al. (2009). Evaluation of RCM experiments for 25 years (and longer). *J. Climate*, 22, 3003–3019.

The table lists the RCMs used in the ensemble focusing on the Carpathian Basin (i.e., Hungary and, if available, the neighboring countries) the responsible institutions and the driving GCMs.

Institutions: Met Office (United Kingdom Met Office) HadRM3D, HadRM3P; CEM (Swiss Federal Institute of Technology Zurich) HadQX016, RICA3; SMHI (Swedish Meteorological and Hydrological Institute) HadRM2Q, RGA; ICP (International Centre of Theoretical Physics) EC-HM1, RGA; MI (Met Office National Centre of Atmospheric Physics) EC-HM2, RGA; MI (Met Office National Centre for Meteology) EC-HM3, RGA; DMI (Danish Meteorological Institute) ARPEGE, HRHAMS; EC-HM3-Q, HRHAMS; CRUE (Centre National de la Recherche Scientifique) ARPEGE, JMA1; ALADIN

Estimated CO₂ level according to the A1B scenario by 2050: 532 ppm, by 2100: 717 ppm based on Nakicenovic & Swart (2000)

Driving GCM: EC-HM3 (IPCC-AR4), HadGEM1 (UKMO), UKMO; ARPEGE (CNRM, FR); HadGEM1 (UKMO)

Bias correction of raw simulation data: 1951–2000

Bartholy, J. (2007). Regional analysis of extreme temperature and precipitation indices for the Carpathian Basin from 1946 to 2001. Global and Regional Climate Model Simulations must be downscaled for local analysis, which can better serve agriculture-related and users' needs. This is especially important in case of precipitation due to the large temporal and spatial variability. Both the high potential risks of drought events on agricultural production, and the possible flood risks in urban areas, as well as the increasing frequency of extreme events over shorter periods, also highlight the importance of this research.

On the basis of evaluating raw RCM projections and of ENSEMBLES model experiments for the period 1951–2000, it was found that the 12 GCMs considered, including daily precipitation values (Held et al., 2009), simulated values usually significantly overestimate the observations in the Carpathian Basin, except in summer. No steady underestimations were found (Pongrácz et al., 2011). These findings of the raw data were confirmed by the bias-corrected ENSEMBLES distribution functions by fitting to the observed distribution (Forniari & Haes, 2009).

Then, the calculated bias-correcting factors are applied to the outputs of the ENSEMBLES experiments for the period 2071–2100. According to the GCM A1B emission scenario (Nakicenovic & Swart, 2000), according to which CO₂ concentration by 2100 is estimated to exceed 700 ppm (more than twice of pre-industrial level), the projected changes in precipitation are significant (Kert et al., 1999) are calculated from the corrected precipitation data sets for each grid point. Projected seasonal changes for 2071–2100 are determined relative to the 1961–1990 reference period and presented in this analysis.
